UAV based SDN system for wireless sensor networks

ABSTRACT

Abstract goes here.

1. INTRODUCTION

Why we are SDN?

Software defined network is able to support flexible network programmability by using programmable data plane and centralized network controller.

OpenFlow focus on wired networks. Challenges and opportunities of SDN for WSN: Challenges: Limited resources of WSN nodes:

- energy
- processing
- memory
- communication

Opportunities:

- Improve resource reuse
- Implement node retasking
- Node and network management
- Enable experiments with new protocols

Why and How we can implement AI? How we combine Ai with other applications?

2. RELATED WORK

2.1 Software Defined Wireless Sensor Networks

Existing SDN for WSN:

- Flow-Sensor
- Sensor OpenFlow
- SDWN
- TinySDN
- SDN-WISE

All of these are evaluated by simulations

Flow-Sensor [MahmudandRahmani2011], Sensor Open-Flow [Luoetal.2012] SDWN [Costanzo et al. 2012] TinySDN [de Oliveira et al. 2014] SDN-WISE [Galluccio et al. 2015]

2.2 Applications for Wireless Sensor Networks

3. ARCHITECTURE

The architecture of the UAV based SDN system for wireless sensor networks.

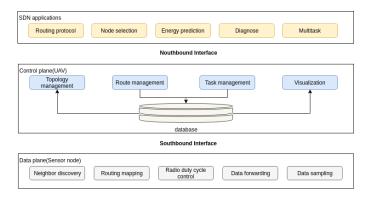

Figure 1: Architecture of the system.

Listing 1: An example of deploy routing algorithm

Table 1: System API

Table 1: System API						
Structure && Function	Description					
Sensor Control Interface						
struct node	Sensor node structure					
struct nodeset	A set of sensor nodes					
struct neighbor_list	Neighbor infomation					
struct energy_item Energy statistic information						
struct flow_table	Flow table					
struct duty_cycle_table						
struct sensor_enable_table	All the nodes's states. Node state: {on,off}					
switch_node(node,state)	Turn on or turn off the node					
get_node_info(node)	Get node's information, including node's position, duty cycle, power, etc.					
set_node_attr(node,attrTag,value)	Set node attribute, including duty cycle, radio strength, etc.					
get_neighborlist(node)	Get the neighbor list of a node					
	UAV Application Interface					
	Routing					
get_topology()	Get the topology of the network					
get_flow_table(node)	Get the flow table of a node					
set_flow(flow,node)	Set the flow of a node					
	AI Node selection					
nodeset simple_selection(nodeset)	Select sensor set by location information					
nodeset SRSSS_selection(dataset) Select sensor set by AI algorithm based on sensing data						
	AI Energy Prediction					
model_selsct(modeltype)	Select an AI model					
model.train(dataset,ratio)	Train an AI model with learning ratio on the data set					
model.test(dataset)	Test the AI model on the data set					
model.predict(node)	Do the energy prediction for a node					
	Multi-tasks					
create_scheduler()	Create a task scheduler					
scheduler.create_buffer()	Create a task buffer					
scheduler.task_buffer_add(task,nodeset)	Add a new task to task buffer					
scheduler.task_buffer_remove(task)	Remove a new task to task buffer					
scheduler.task_buffer_update(task,nodeset)	Update a task to task buffer with a new nodeset					
scheduler.task_update()	Schedule the added or removed tasks in the buffer					
Diagnosis						
detect()	Detect problematic region with probes					
get_topical_topology(nodeset)						
diagnose_network(topology,nodeset)	Diagnose the failure nodes or lossy links

4. APPLICATIONS

4.1 Overview

Traditional applications can not achieve complicated and efficient goals due to the limited processing power and memory space of sensors.

In XX, applications for wireless sensor networks are inspired by greater potential with the UAV based SDN controller. The central controller helps sensors execute complex calculations such as AI model training, as well as store global information. Besides, UAVs have flexible features and can deploy tasks to sensors by one-hop communication directly. Thus it enables the sensor network to achieve much more intelligent applications.

In XX, applications can be found for a variety of purposes, including routing, AI node selection, AI energy prediction, multi-tasks and network diagnosis. We design all these applications and provide easy-to-use interfaces to users as in Table 1.

4.3 AI Node Selection

4.3.1 Motivation

It is inevitable that there will be a part of redundant sensors when deploying a practical wireless sensor network. These redundant nodes have overlaps of observation regions, and what makes the matter worse is that redundant nodes may cause great communication interference. Therefore it is significant to select proper sensors to avoid data redundancy and save the sensor network energy consumption.

In XX, we provide the node selection application to users. The SDN controller executes the selecting algorithm and send the control instructions to activate the selected nodes.

4.3.2 Design

Our XX system provide two main node selecting methods: greedy selection algorithm and SRSSS algorithm. This application will be extended to more elegant algorithms in our future work.

Greedy selection algorithm. We first provide a simple method to select the redundant nodes by a greedy selection algorithm, as described in 1. The key idea is to select nodes as less as possible to coverage the whole area based on the location and sensing range.

Spatially regularized streaming sensor selection (SRSSS). To realize more intelligent and effective sensor selection, we introduce an AI algorithm named spatially regularized streaming sensor selection (SRSSS). SRSSS is a state-of-the-art sensor selection algorithm proposed in [1].

Different from the greedy selection algorithm, SRSSS is a multi-variate interpolation framework and focuses on selecting a subset of sensors in a streaming scenario to minimize collected information redundancy.

The aim of SRSSS is to optimize its objective function which is an equation given certain constraints of collected information, location and energy consumption The objective function is formulated as:

Algorithm 1 Greedy Selection Algorithm

```
1: Input: Sensor set N, Selected set M, Target area
    \Omega, Covering area \Phi;
 2: Initialize : M = \emptyset, \Phi = \emptyset
 3: while M \neq N do
       if \Phi = \Omega then
 4:
 5:
         break; \\ selected set has been found
 6:
 7:
       if \forall n_i \in (N-M) : range(n_i) \subset \Phi then
         break;\\ Cannot cover the target area;
 8:
 9:
10:
       Find n_i : argmax(\Phi \cap range(n)), n_i \in (N-M);
       \Phi = \Phi \cup n_i
11:
12: end while
13: Output: M;
```

$$(W_{k+1}, z_{k+1})$$

$$= arg \min_{W,z} \sum_{i=1}^{k} \mu^{k-i} ||X_k^i D_z W(I - D_z) - X_k^i (I - D_z)||_2^2$$

$$+ \alpha \sum_{i,j=1}^{n} ||y_i - y_j||_2 |W_{i,j}| - \beta \sum_{i,j=1}^{n} ||y_i - y_j||_2 z_i z_j + \lambda ||W||_F^2$$

$$s.t.z = [z_1, ..., z_n] \in \{0, 1\}^n, c^T z \le P$$

AI helps creating smarter sensor systems.

AI systems have been improving, and new advances in machine intelligence are creating seamless interactions between people and digital sensor systems.

In sensor systems, applications can be found for a variety of tasks, including selection of sensor inputs, interpreting signals, condition monitoring, fault diagnosis, machine and process control, machine design, process planning, production scheduling, and system configuring. Some examples of specific tasks undertaken by expert systems are: * Assembly * Automatic programming * Controlling intelligent complex vehicles * Planning inspection * Predicting risk of disease * Selecting tools and machining strategies * Sequence planning * Controlling plant growth.

The tools and methods described have minimal computation complexity and can be implemented on small assembly lines, single robots, or systems with low-capability microcontrollers. These novel approaches proposed use ambient intelligence and the mixing of different AI tools in an effort to use the best of each technology. The concepts are generically applicable across many processes.

minimum energy, data loss, reliability, robustness, etc., in place during the design and operation of wireless sensor networks

a specific set of protocols for medium access, local-

ization and positioning, time synchronization, topology control, security and routing are identified based on the current configuration of the network, the requirements of the application and the topology of their deployment.

4.4 AI Energy Prediction

4.4.1 Motivation

4.4.2 Design

4.5 Multi-tasks

4.5.1 Motivation

Wireless sensor networks (WSN) generally comprise of a group of spatially dispersed sensors. In a wireless sensor network, sensor nodes are equipped with various types of sensors monitoring and recording environmental conditions like temperature, sound, sunlight, humidity, etc.

A given sensing task involves multiple sensors to achieve a certain quality-of-sensing. Generally, an efficient task scheduling for the nodes is that nodes are able to perform multiple tasks simultaneously. For example, sensors deployed in a grove are assigned tasks to collect sunlight, temperature and humidity data and these tasks require different number of nodes with respective sensing range, rate and duration. However, traditional sensor networks are not suitable to conduct this multi-tasks due to the limitations of computation complexity for task arrangement of each node.

In our XX system, we implement the multi-tasks application with the help of the central controller. The SDN controller maintains programmable task scheduling and management modules while sensor nodes are loaded with interfaces to receive task control instructions.

4.5.2 Design

A deployed wireless sensor networks are usually assigned

A sensor node may have different sensing ranges for different tasks.

There are several practical requirements.

Different tasks have different requirements, including time, sensing range, sensing ratio, etc.

For example tasks like sunlight collection only need to be carried out during the daytime.

Our system provide a task scheduling to

Sensors are usually assigned multi-tasks.

Sensors are assigned tasks to monitor a specific area.

Table 4: Task Buffer

Task ID	Node set	Sensing rate	Sensing range	Sensing duration
10011 11	11000	201121112	201101118 1011180	Dombing darage

Different tasks have different requirements, i.e.

- Node set. Users can assign tasks to
- Sensing rate.
- Sensing range. The maximum distance that a node can detect.
- Sensing duration. The sensing time from start to end. There is no need to collect sunlight data at night.

Task scheduler do the arrangement.

Task buffer.

Task queue.

Scheduling table.
